I. INTRODUCTION

This report presents the results of an investigation of the fire performance characteristics of an exterior wall system submitted by Insteel Construction Systems, of Brunswick, Georgia. This report includes a description of the test materials, procedures used, and results. The results presented in this report apply only to the material tested which the Client claims to be a representative sample of the materials described in this report. The possibility of product variability has not been assessed.

This test was conducted in accordance with the general procedure described in Fire Research Group Report No. 78-13, University of California (Berkeley), December 1978, "A Summary Description of the Modified ASTM E108 Test Procedure."

This procedure is used to measure and describe the properties of materials, products, or assemblies in response to heat and flame under controlled laboratory conditions, and should not be used to describe or appraise the fire hazard or fire risk of materials, products, or assemblies under actual fire conditions. However, results of this test may be used as elements of a fire risk assessment which takes into account all of the factors which are pertinent to an assessment of the fire hazard of a particular end use.

There are no established criteria for the Modified E108 test. A proposed standard for this test procedure, where conditions for acceptable performance are defined, are contained in the 1984 Annual Report of the Code Development Committees, 62nd Annual Education and Code Development Conference, International Conference of Building Officials, September 1984. These conditions are as follows:

Section 17.2206. The performance of a test assembly shall be judged on the basis of visual observations both during and after the test in conjunction with temperature data. An exterior wall assembly shall be considered as meeting the requirements for acceptable performance if during the 15-minute test period:

1. Significant flame propagation does not occur over the exterior face of the test panel. Small, intermittent flames along seams, joints, or on the exterior face of the test assembly in the region of direct flame exposure may be ignored.
2. Significant flame propagation shall not occur vertically or laterally through the core insulation. Damage to the core insulation shall not extend to the limits of the test panels. Flame propagation may be judged to occur within

Department of Fire Technology

the test panels when temperatures within the insulation core outside the region of direct flame exposure exceed 750°F.

II. OBJECTIVE

The objective of this program was to evaluate an exterior wall system incorporating potentially combustible elements when tested in accordance with the Modified E108 test procedure.

III. TEST MATERIALS

The test panels were built at Southwest Research Institute by the Client. The system was described as INSTEEL 3-D WALL PANELS. Two wall assemblies were tested in this program. One wall assembly was tested in a damaged condition and the other undamaged. The panels were assembled in November 1989.

Each 6 x 10-ft wall panel consisted of a three-dimensional welded wire space frame integrated with a polystyrene insulation core. This reinforcement/insulation module was placed in position, and wythes of concrete were applied to both sides. Diagonal cross wires were welded to the welded wire fabric on each side. This is shown in Appendix B, Figure A.

According to the Client, three different configurations of reinforcement/insulation module (RIM) are manufactured (see Appendix B, Figures B, C, and D). The system tested in this program had a 2-1/2-in. insulation and a RIM thickness of 4 in. The concrete face was 1-1/2-in. thick, and the back was 3/4-in. The edges of the walls were 1/4-in. thick covered with concrete.

IV. TEST PROCEDURE

The test was designed to simulate a fire exposure to the exterior portion of a wall by a flame that emanates from an opening such as a window. The equipment utilized is the same as that described in ASTM E108 test procedure, "Standard Methods of Fire Tests of Roof Coverings." In these evaluations, the test specimen was positioned vertically, as opposed to being sloped as in the roof test, in order to simulate a fire exposure of an exterior wall system. Sketches of the test apparatus are shown in Figures 1 and 2. Figure 1 shows that

Department of Fire Technology

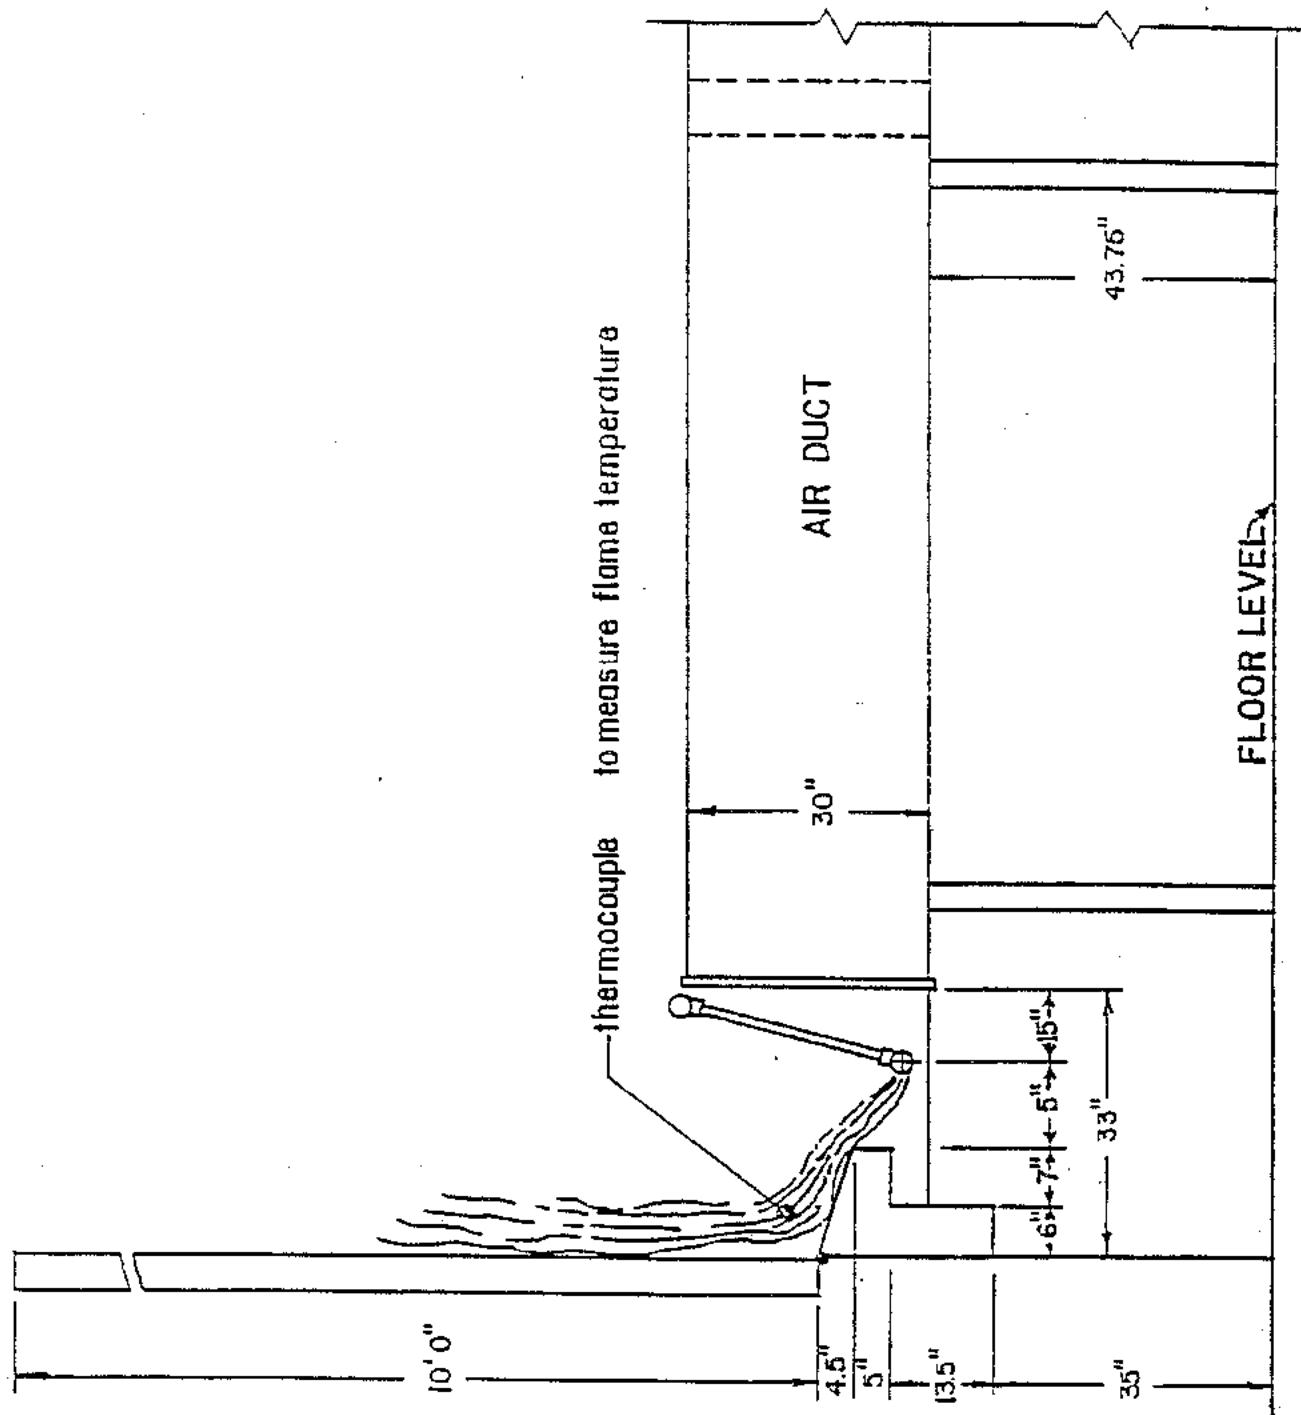

FIGURE 1. SCHEMATIC DIAGRAM OF MODIFIED E1 APPARATUS FOR EVALUATION OF VERTICAL FIRE SPREAD

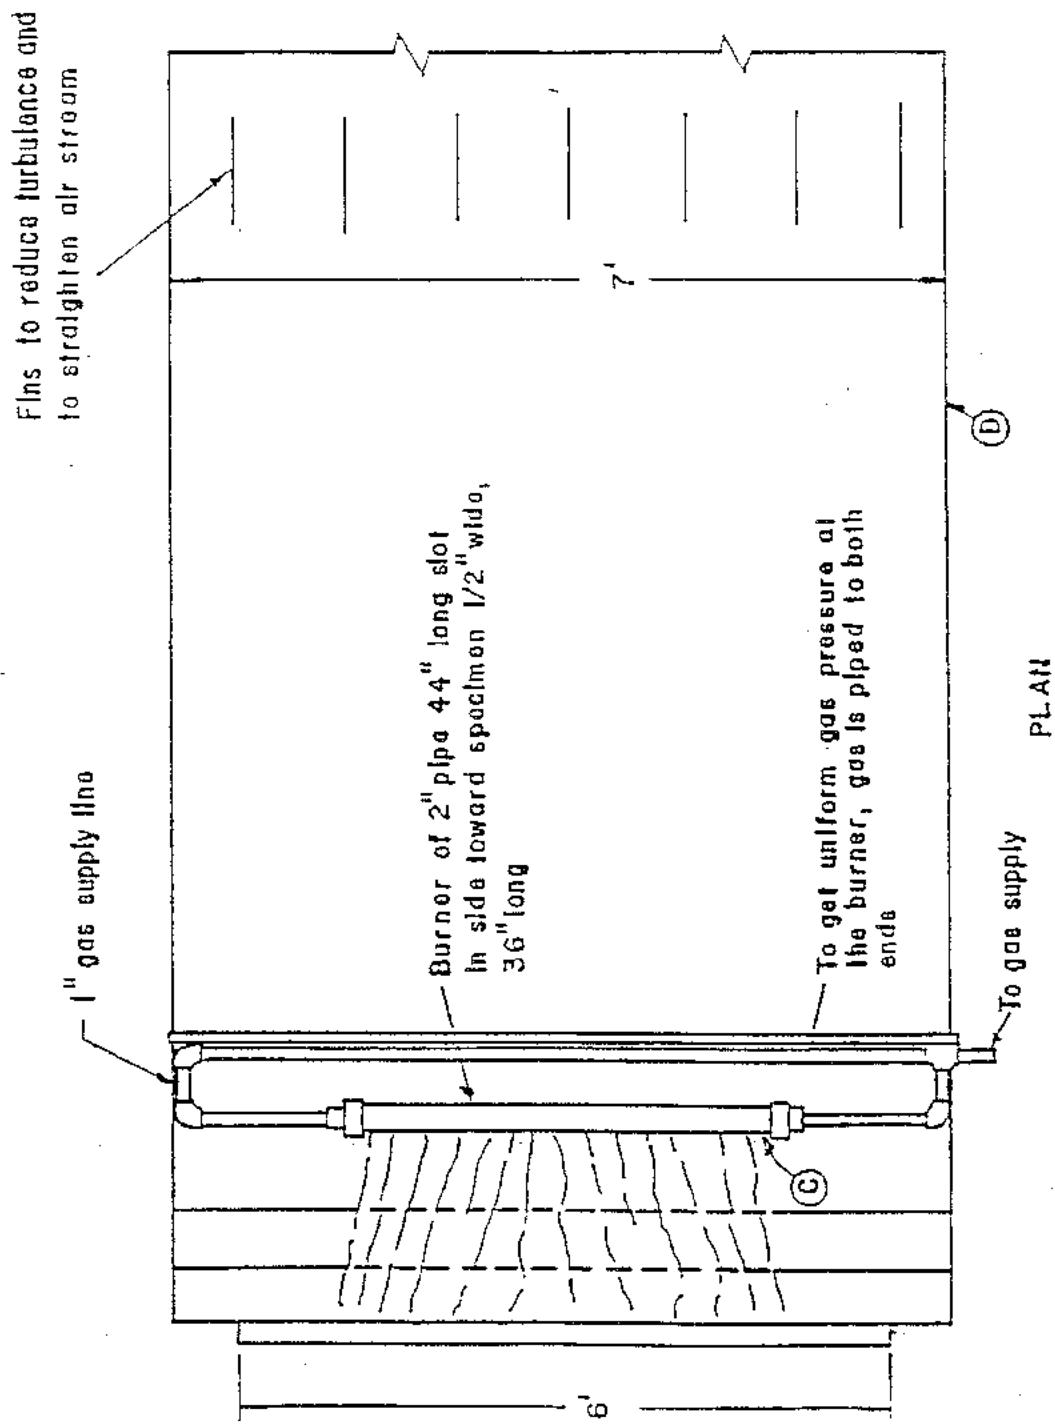

FIGURE 2. SCHEMATIC DIAGRAM OF VERTICAL PANEL TEST

the 6 x 10-ft test specimen is placed in a vertical position with the exposed face in the same position as the leading edge of a roof test specimen with respect to the simulated eave.

The air duct is open to the outside of the laboratory. An exhaust fan in the ceiling above the test specimen is used to pull air from the test room. The air velocity up the face of the test specimen is approximately 3 mph. The flame from the burner "attaches" to the specimen imposing a direct flame exposure.

Each panel was instrumented with thermocouples placed at various locations on the exposed face of the test panel, the interface of the insulation and exposed surface, and the insulation/unexposed concrete wythe interface. Figure 3 shows the thermocouple locations.

The panels were exposed to the fire source for the required 15 minutes.

V. CALIBRATION PROCEDURE

The calibration of the fire exposure is accomplished using a 6 x 8-ft panel constructed from Marinite board in order to obtain temperature and heat flux data when exposed to a 5- to 6-ft flame.

In the ASTM E108 and the Modified E108, natural gas (1000 Btu/ft³) is the fuel source for the burner. The gas flow rate required to produce a 5- to 6-ft flame was recorded during the calibration test and was then used during each subsequent test to ensure reproducibility of the flame source.

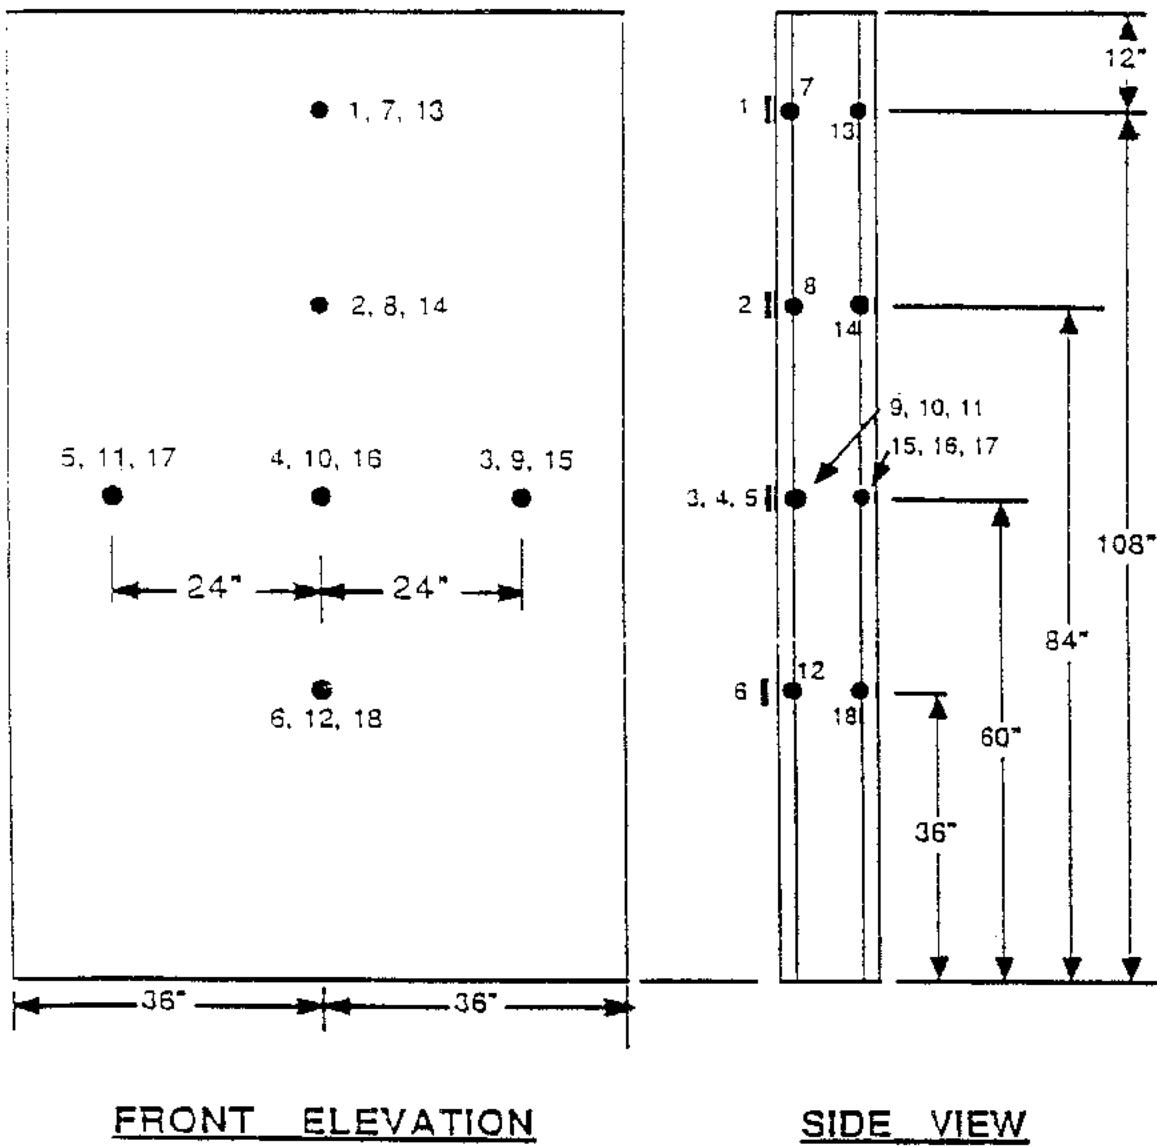

The calibration panel was instrumented as shown in Figure 4. Five 24-gauge type K thermocouples and three total heat flux transducers were mounted flush with the surface of the panel. A thermocouple was also located in the flame zone at the base of the mounted specimen as shown in Figure 3.

VI. TEST RESULTS

The test was conducted on December 13, 1989. The gas burner flame reached 5- to 6-ft levels during the tests, as specified by the test procedure. Temperature data are presented in Appendix A. Thermocouple nos. 2 through 6 were located on the exposed face

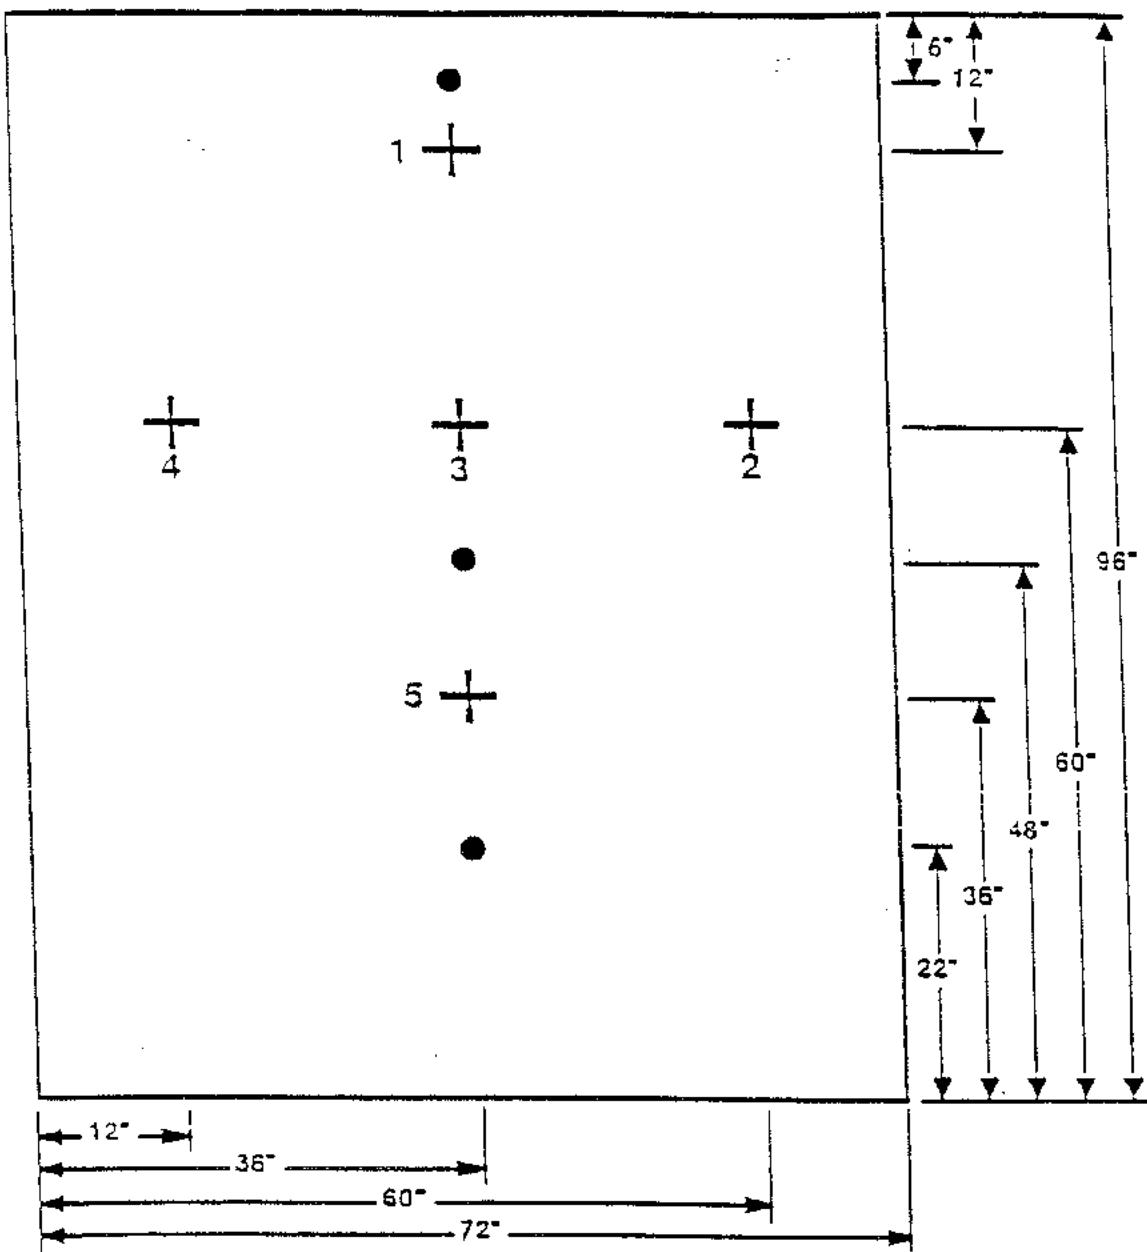

Department of Fire Technology

NOTE:

- Thermocouples 1-6 located on the finished surface
- Thermocouples 7-12 located between the insulation and finished surface
- Thermocouples 13-18 located between the insulation and the gypsum wallboard

FIGURE 3. LOCATION OF THERMOCOUPLES

+ Bare Thermocouple on Surface

Scale: 3/4" = 1"

● Watercooled Calorimeters

Placement of Instrumentation

FIGURE 4.

of the panel. Thermocouple nos. 7 through 12 were placed on the interface of the insulation and exposed surface, and Thermocouple nos. 13 through 18 were located on the insulation/concrete wythes interface. Thermocouple No. 1 on the undamaged specimen was not located as specified by the test procedure. Therefore, the data for this thermocouple was omitted. This omission did not have any effect on the evaluation of the fire performance characteristics of the wall system.

Observations made during the test are presented in Appendix C. Photographs showing the damage sustained by the specimens as a result of the fire exposure are presented in Figures 5 and 6.

Specimen No. 1: Undamaged--smoke developed during the test period was very light. There was no flame propagation over the exterior face outside the area of direct flame contact. Interior flame propagation did not occur in any direction. The maximum temperature within the insulation outside the region of direct flame contact was 42°F.

Specimen No. 2: Damaged--smoke developed during the test period was light. Flame propagation did not occur over the exterior face outside the area of direct flame contact. Interior flame propagation did not occur in any direction. The maximum temperature within the insulation outside the region of direct flame contact was 61°F.
